In a nutshell

- Main Purpose: The Alternating Direction Method of Multipliers (ADMM) is an algorithm that solves convex optimization problems.
- Main Principle: ADMM algorithm breaks problems into smaller pieces, each of which are then easier to handle.
- Motivation: found wide application in the last decade in areas such as large-scale problems arising in statistics and machine learning.
 Reason: ADMM is well suited to distributed convex optimization
- Origin: developed in the 1970s, with roots in the 1950s.
 Related to many other algorithms: dual decomposition, the method of multipliers, Douglas-Rachford splitting, proximal methods, and others.
- About the roadmap of this course: we first introduce some basic
 assumptions. Before introducing ADMM itself, two methods need to
 be presented first, namely Dual decomposition and Method of
 Multipliers. ADMM is born from the desire to get the best of those
 two methods.

Roadmap

- Assumptions
- 2 Dual decomposition
- Method of Multipliers
- 4 Alternating Direction Method of Multipliers
- Commom patterns
- 6 Examples
- Appendices
 - Appendix 1
 - Appendix 2

Blanket assumptions

this course: underlying space is the Euclidean space \mathbb{R}^n , a particular case of Hilbert space \mathcal{X} of finite dimension n, that is, a Banach space equipped with:

- an inner product $\langle .,. \rangle$, here we consider the dot product $\langle x,y \rangle = \sum_{i=1}^{n} x_{i} y_{i}$ for $x,y \in \mathbb{R}^{n}$,
- induced norm $\|.\| = \sqrt{\langle .,. \rangle}$

Set of assumptions on functions

Through this course:

- focus on the minimization of a function *f* over a convex set by basically tackling its dual problem or a modified version of it ("Augmented").
- important to always keep in mind the set of assumptions made on the functions, in particular on *f* (the primal objective function).
- The most important assumptions will be highlighted in red when needed
- The derived results (mainly linked to the convergence results of the algorithms discussed in the present document) are only valid in the set of assumptions considered (= the paradigm).

Roadmap

- Assumptions

 - Appendix 1
 - Appendix 2

Dual Problem

• Given $A \in \mathbb{R}^{m \times n}$, $b \in \mathbb{R}^m$ and $f : \mathbb{R}^n \to \mathbb{R}$ a convex function , we are interested in solving:

$$\min_{\mathbf{x} \in \mathbb{R}^n} f(\mathbf{x}) \\
\text{subject to} \quad A\mathbf{x} = \mathbf{b}, \tag{1}$$

- Form the **Lagrangian** function: $L(x,y) = f(x) + \langle y, Ax b \rangle$ where Ax b is the residual and $y \in \mathbb{R}^m$ are referred to as Lagrangian multipliers (= dual variables).
 - What does it mean ?: we allow the constraints to be violated, but there is a price to pay which is given by the term $\langle y, Ax b \rangle$.

Dual Problem

- Build the **dual** function: $g(y) := \inf_x L(x, y)$ Particular structure for g(y): the dual function is always concave.
- Dual Problem: maximize g(y)
- Let us assume that the maximization goes well. By denoting $y^* := \underset{y \in \mathbb{R}^m}{\operatorname{argmax}} g(y)$, we may recover $x^* := \underset{x \in \mathbb{R}^n}{\operatorname{argmin}} L(x, y^*)$.

Does this approach always work? : NO. Actually this may fail even for linear problems. However, with enough and appropriate assumptions, this method works (ex: minimal curvature ← not too "flat").

Solve the Dual Problem: the Dual ascent scheme

- How to maximize the dual function ? \rightarrow Use an **ascent** gradient method: $y^{k+1} := y^k + \alpha^k \nabla g(y^k)$ where α^k is the step size (positive scalar), k denotes the iteration counter, and g(y) is assumed to be differentiable w.r.t. y^1 .
- $\nabla g(y^k) = A\tilde{x} b$, where $\tilde{x} := \underset{x \in \mathbb{R}^n}{\operatorname{argmin}} L(x, y^k)$
- Dual ascent method is an iterative scheme such that at each iteration we have two steps:
- $y^{k+1} := y^k + \alpha^k (Ax^{k+1} b)$ %dual update

¹it requires *f* to be closed and strictly convex, if not, a subgradient method should be used, see Appendix 1 for more details.

Solve the Dual Problem: the Dual ascent scheme

Few remarks:

- Step 1: consider L, fix the dual vector and minimize over x.
- Step 2: calculate the residual
 - If the residual is zero, optimality reached → stop
 - Otherwise, update the dual variables by some positive number times
 the residual
- This method works, but again with many strong assumptions.
- Why do we solve the dual instead of the primal ?: The reason has to do with the notion of dual decomposition...

Additional Assumption: Separability

Assume that function f is separable:

$$f(x) = f_1(x_1) + ... + f_N(x_N), \quad x := (x_1, ..., x_N)^T$$

where $1 \le N \le n$.

It means that *f* can be expressed as a sum of functions of individual blocks.

- then L is separable in x: $L(x,y) = \sum_{i}^{N} L_{i}(x_{i},y) \langle y,b \rangle$ with $L_{i}(x_{i},y) = f_{i}(x_{i}) + \langle y,A_{i}x_{i} \rangle$ and $A_{i} \in \mathbb{R}^{m \times q(i)}$ where q(i) denotes the size of block x_{i} .
- x-minimization step from dual ascent scheme splits into N independent problems:

$$x_i^{k+1} := \underset{x_i \in \mathbb{R}^{q(i)}}{\operatorname{argmin}} L_i(x_i, y^k)$$

....which can be solved in parallel!

Dual decomposition

Dual Decomposition algorithm (Everett, Dantzig, Wolfe, Benders, 1960-65) is:

- $y^{k+1} := y^k + \alpha^k (\sum_i^N A_i x_i^{k+1} b)$ %dual update
 - Step 1: minimization of each Lagrangian term L_i separately
- Step 2: gathering of the contributions to the equality constraints
 If the residual is zero → Stop
 Otherwise, update of the dual variables

Dual decomposition

- What is required ?:
 - \bigcirc a scattering of the dual variables (y^k) ,
 - 2 update of x_i in parallel,
 - 3 a gathering $(\sum_{i}^{N} A_{i} x_{i}^{k+1})$. (provides coordination)
- → Distributed (convex) optimization!
 - → Allow to solve large problems!
- works with a lot of assumptions; often slow.
 Reason: to have interesting properties on g(y) for minimization schemes, it requires strong assumptions on f.
 (Refer to Appendix 1 for more details.)

Roadmap

- Assumptions
- 2 Dual decomposition
- Method of Multipliers
- 4 Alternating Direction Method of Multipliers
- 6 Commom patterns
- Examples
- Appendices
 - Appendix 1
 - Appendix 2

Method of Multipliers

that it would work for problems as linear problems, but not only !)

Goal: develop a method to make the Dual Ascent more robust (so

Main idea: use an augmented Lagrangian (Hestenes, Powell, 1969):

$$L_{\rho}(x,y) = f(x) + \langle y, Ax - b \rangle + \frac{\rho}{2} ||Ax - b||_2^2$$

where $\rho > 0$ is a constant (the penalty parameter for the constraint).

- Method of Multipliers (Hestenes, Powell; analysis in Bertsekas in 1982)
- 2 $y^{k+1} := y^k + \rho(Ax^{k+1} b)$ %dual update with step length ρ

Method of Multipliers: Remarks

An interesting and alternative introduction of the concept: the method modifies the problem (1) as follows:

$$\min_{\mathbf{x} \in \mathbb{R}^n} f(\mathbf{x}) + \frac{\rho}{2} ||A\mathbf{x} - \mathbf{b}||_2^2$$
subject to $A\mathbf{x} = \mathbf{b}$, (2)

Clearly extra term $\frac{\rho}{2}||Ax - b||_2^2$ does not change problem. On top of that:

Proposition

Let h = f + g where f is convex function and g is a strongly convex function, then h is strongly convex function.

Hence, assuming, e.g., A has full rank, primal objective is strongly convex of parameter $\rho\sigma_{\min}^2(A)$ (f is then also strictly convex), the dual function gets good properties for the use of dual ascent method. (See Appendix 1)

Method of Multipliers: Remarks

Differences with Dual Ascent method:

- Addition of a nonnegative term which is a quadratic penalty (always a cost) to the Lagrangian function.
- The gain for the dual update has a very specific step size = the penalty parameter ρ .

Why ?...

Method of Multipliers: dual update step

- Let us write the first-order optimality conditions for Problem (1) (for f differentiable):
 - \bigcirc $Ax^* b = 0$ (Primal feasibility),
- Step 1 from **Method of Multipliers**: x^{k+1} is the minimizer of $L_{\rho}(x, y^k)$, therefore it satisfies the following condition (unconstrained optimization problem):

$$0 = \nabla_{x} L_{\rho}(x^{k+1}, y^{k})$$

$$= \nabla_{x} f(x^{k+1}) + A^{T} y^{k} + \rho (A^{T} A x^{k+1} - A^{T} b)$$

$$= \nabla_{x} f(x^{k+1}) + A^{T} (y^{k} + \rho (A x^{k+1} - b))$$

$$= \nabla_{x} f(x^{k+1}) + A^{T} y^{k+1}$$
(3)

Method of Multipliers: dual update step

algorithm generates iterates (x^{k+1}, y^{k+1}) that are *dual feasible*. • As the algorithm progresses, we hope that the residual $Ax^{k+1} - b \rightarrow 0$

• With step size ρ , after each iteration of the Method of Multipliers,

• As the algorithm progresses, we hope that the residual $Ax^{k+1} - b \rightarrow 0$ to obtain the primal feasibility and hence reach the optimality.

Method of Multipliers: take-home messages

This method is similar to dual decomposition (particular case of dual ascent for which *f* is separable) but with two differences that induce:

- An advantage: Adding the quadratic term 2 allows the Method of Multipliers to converge under less strong assumptions (it basically works in any cases), for instance f can be non-differentiable, take on value $+\infty$ in the case f is an indicator function for a convex set $C \subseteq \mathbb{R}^n$.
- A drawback: quadratic penalty term destroys splitting for the update of x (so, cannot do decomposition).

In summary: robust but non-separable.

²Recently, other types of augmented terms gained interests such as the Bregman divergences or entropy.

Roadmap

- Assumptions
- 2 Dual decomposition

- Alternating Direction Method of Multipliers
- 6 Commom patterns
- 6 Examples
- Appendices
 - Appendix 1
 - Appendix 2

ADMM

- Goal: develop a method
 - with the good robustness of method of multipliers.
 - which can support decomposition for allowing distributed optimization
- proposed by Gabay, Mercier, Glowinski, Marrocco in 1976 (however, we have discovered in 80s that **ADMM** could be re-derived from materials from the 50s..., probably in Moscow:)).

The main point is: this is not new.

ADMM - (Western) Problem form

• Given *f* and *g* convex functions, we are interested in solving:

$$\min_{x,z} f(x) + g(z)
\text{subject to} Ax + Bz = c,$$
(4)

where:

- x and z are two sets of variables (previous variable x splitted into two groups),
- the objective is required to be separable across x and z,
- \odot the general equality constraint links x and z.

ADMM - Algorithm

• Build the augmented Lagrangian:

$$L_{
ho}(x,z,y)=f(x)+g(z)+\langle y,Ax+Bz-c
angle +rac{
ho}{2}\|Ax+Bz-c\|_2^2$$

- **ADMM**: Iterative scheme, at each iteration → three steps:
- $x^{k+1} := \operatorname{argmin} \ L_{\rho}(x, z^k, y^k)$ %x-minimization
- $z^{k+1} := \underset{z}{\operatorname{argmin}} \quad L_{\rho}(x^{k+1}, z, y^k)$ %z-minimization
- $y^{k+1} := y^k + \rho (Ax^{k+1} + Bz^{k+1} c)$ %dual update with step length ρ

ADMM - Remarks

- If we minimize over x and z jointly, **ADMM** boils down to the **Method** of **Multipliers**.
- We get **Decomposition** since we minimize over x with z fixed, and vice versa.

By the way: we are free to minimize over x and z as many times as we want before updating the dual variables.

ADMM - Optimality conditions

- Let us write the first-order optimality conditions for Problem (4) (for f and g differentiable):

 - $\nabla_x L(x^*, z^*, y^*) = \nabla_x f(x^*) + A^T y^* = 0 \text{ (x-Dual feasibility)}.$
 - $\nabla_z L(x^*, z^*, y^*) = \nabla_z g(z^*) + B^T y^* = 0$ (z-Dual feasibility).
- Step 2 from **ADMM**: z^{k+1} is the minimizer of $L_{\rho}(x^{k+1}, z, y^k)$, therefore it satisfies the following condition (unconstrained optimization problem):

$$0 = \nabla_{z} L_{\rho}(x^{k+1}, z^{k+1}, y^{k})$$

$$= \nabla_{z} g(z^{k+1}) + B^{T} y^{k} + \rho B^{T} (Ax^{k+1} + Bz^{k+1} - c)$$

$$= \nabla_{z} g(z^{k+1}) + B^{T} (y^{k} + \rho (Ax^{k+1} + Bz^{k+1} - c))$$

$$= \nabla_{x} g(z^{k+1}) + B^{T} y^{k+1}$$
(5)

ADMM - Optimality conditions

- With step size ρ , after each iteration of **ADMM**, algorithm generates iterates (x^{k+1} , z^{k+1} , y^{k+1}) that are *z-dual feasible*.
- As the algorithm progresses, we hope that:
 - the residual $Ax^{k+1} + Bz^{k+1} c \rightarrow 0$ to obtain the primal feasibility,
 - $(x^{k+1}, z^{k+1}, y^{k+1})$ are x-dual feasible.

and hence reach the optimality.

ADMM - The scaled dual form

It is often easier to express the **ADMM** algorithm in scaled form, where we replace the dual variable y by a scaled variable $u = \frac{y}{\rho}$

• Idea: Combine linear and quadratic terms in augmented Lagrangian:

$$L_{\rho}(x, z, y) = f(x) + g(z) + \langle y, Ax + Bz - c \rangle + \frac{\rho}{2} ||Ax + Bz - c||_{2}^{2}$$
$$= f(x) + g(z) + \frac{\rho}{2} ||Ax + Bz - c + u||_{2}^{2} + \text{const}$$

- In this form, the ADMM steps are:
- 2 $z^{k+1} := \underset{z}{\operatorname{argmin}} \left(g(z) + \frac{\rho}{2} ||Ax^{k+1} + Bz c + u^k||_2^2 \right) \%z \underset{z}{\operatorname{minimization}}$
- $u^{k+1} := u^k + (Ax^{k+1} + Bz^{k+1} c)$ %dual update

ADMM - The scaled dual form

Note that here the kth iterate u^{k+1} is just given by a running sum of residuals:

$$u^{k+1} = u^0 + \sum_{i=1}^{k+1} (Ax^i + Bz^i - c)$$

= $u^0 + A \sum_{i=1}^{k+1} x^i + B \sum_{i=1}^{k+1} z^i - (k+1)c$

ADMM - Convergence guarantees

- Under (very little!) assumptions:
 - on f and g:
 - are convex,
 - ② are closed: a function $I: \mathbb{R}^n \to \mathbb{R}$ is closed if its epigraph, denoted and defined by $\operatorname{epi}(f) = \{(x, t) | f(x) \le t \text{ for } x \in \mathbb{R}^n, t \in \mathbb{R}\}$, is closed.
 - are proper: a function I is called proper if I does not take the value -∞ and dom(I) is nonempty.
 - L₀ has a saddle point (roughly speaking; the primal problem needs to have a solution, otherwise there is no point)
 These assumptions do not require A and B to be full rank.
- the **ADMM** iterates satisfy, for any $\rho > 0$:
 - **1** Residual convergence: $r^k = Ax^k + Bz^k c \rightarrow 0$ as $k \rightarrow \infty$, i.e., primal iterates approach feasibility.
 - ② Objective convergence: $f(x^k) + g(z^k) \rightarrow f^* + g^*$, where $f^* + g^*$ is the optimal primal objective value.
 - **3** Dual convergence: $u^k \to u^*$, where u^* is a dual solution.

ADMM - Convergence guarantees

- The convergence garantees are very carefully worded. Many things are not said because they are FALSE, for instance:

 - 2 z^k converges \rightarrow FALSE
 - (x^k, z^k) converge to the optimal set \rightarrow FALSE
 - (x^k, z^k) converge to (x^*, z^*) which are the optimal primal solutions \rightarrow FALSE

In summary: we do not generically get primal convergence, but this is true under more assumptions (*Question: is it that relevant?*Because we are loosing the all point of this methods that work "no matter what" + stopping criterion?).

 Convergence rate: roughly, ADMM behaves like first-order method (see Appendix 1 for more details).
 Theory still being developed, see, e.g., in Hong and Luo (2012), Deng and Yin (2012), lutzeler et al. (2014), Nishihara et al. (2015)

ADMM - Practicalities and tricks

- In practice, ADMM obtains a relatively accurate solution in a handful
 of iterations, but requires many, many iterations for a highly accurate
 solution. Hence it behaves more like a first-order method than a
 second-order method.
- Choice of ρ , can greatly influence practical convergence of **ADMM**:
 - ho is too large ightarrow not enough emphasis on minimizing f+g
 - $m{\circ}\
 ho$ is too small ightarrow not enough emphasis on feasibility
 - (Boyd et al, 2010) give a strategy for varying ρ that is useful in practice (but without convergence guarantees).
- Like deriving duals, transforming a problem into one that ADMM can handle is sometimes a bit subtle, since different forms can lead to different algorithms.

ADMM - Practicalities and tricks

We called the method **ADMM** but it turns out that **ADMM** is related to and exactly the same as many other methods, let us cite a few:

- Identical to the Douglas-Rachford operators splitting method (by choosing the right operators and split in the right way).
 (Douglas, Peaceman, Rachford, Lions, Mercier,...,1950s, 1979)
- proximal point algorithm (applied to the right operator to figure out) (Rockafellar 1976)
- Dykstra's alternating projections algorithm (1983),
- Spingarn's method of partial inverses (1985)
- Bregman iterative methods (2008-present) (substitute the quadratic term by Bregman divergence, more general).

Why? How is it that different well-known algorithms are actually the "same"?: It is complicated enough to transform (reorder, change the variables, select right operator, etc) algorithm A to algorithm B and certify they are in fact the same.

Roadmap

- Assumptions
- Dual decomposition
- Method of Multipliers
- 4 Alternating Direction Method of Multipliers
- Commom patterns
- Examples
- Appendices
 - Appendix 1
 - Appendix 2

Common patterns

Let us consider the **ADMM** scaled form,

- x-update step from **ADMM** requires minimizing $f(x) + \frac{\rho}{2}||Ax v||_2^2$ with $v = -Bz^k + c u^k$ is a constant during x-update.³
- similar for z-update
- several special cases come up often (particular choice for g and/or for A, B and c)
- can simplify the update by exploiting the structure of these special cases

³Note that **ADMM** can be seen as a meta-algorithm, we are dealing with more abstract objects here compared to classical optimization algorithms where you end up working with primitives such as gradients or subgradients. Except for special cases, the operators are higher levels, they require to minimize a quadratic augmented function (can be really challenging!).

Decomposition

Assume that function f is separable:

$$f(x) = f_1(x_1) + ... + f_N(x_N), \quad x := (x_1, ..., x_N)^T$$

where 1 < N < n.

- Assume that $A^T A$ is block diagonal w.r.t. blocks $x := (x_1, ..., x_N)^T$, (as a simple illustration consider the case A = I),
- then the $f(x) + \frac{\rho}{2} ||Ax v||_2^2$ splits into N components, \rightarrow update of x_i in parallel, for i = 1, ..., N.

Quadratic objective

f(x) = 1/2⟨x, Px⟩ + ⟨q, x⟩ + r
 → x-update requires to minimize a quadratic without constraints, can be done in closed form:x^{k+1} is the solution of min_x I(x) := 1/2⟨x, Px⟩ + ⟨q, x⟩ + r + ^ρ/₂||Ax - v||²₂ where v = -Bz^k + c - u^k is a constant. Hence we are looking for x such that:

$$0 = \nabla I(x)$$

= $(P + \rho A^T A)x + (q - \rho A^T v)$

Hence
$$x^{k+1} := (P + \rho A^T A)^{-1} (\rho A^T v - q)$$

- The problem: the computation of the inverse!
 - Depending on sparsity patterns, you may use matrix inversion lemma:

$$(P + \rho A^T A)^{-1} = P^{-1} - \rho P^{-1} A^T (I + \rho A P^{-1} A^T)^{-1} A P^{-1}$$

• Dense case: (direct method) cache factorization of $(P + \rho A^T A)$ (LU or Cholesky if symmetric pd).

Connection to proximal operators

Consider

$$\min_{x} f(x) + g(x) \iff \min_{x,z} f(x) + g(z) \text{ subject to } x - z = 0$$

a particular case of Problem (4) with $A = I_{n \times n}$, $B = -I_{n \times n}$ and c = 0

Build the augmented Lagrangian (scaled form):

$$L_{\rho}(x,z,y) = f(x) + g(z) + \frac{\rho}{2}||x-z+u||_2^2$$

• Consider x-update with $v^k = z^k - u^k$:

$$x^{k+1} := \underset{x}{\operatorname{argmin}} \left(f(x) + \frac{\rho}{2} ||x - v^k||_2^2 \right)$$

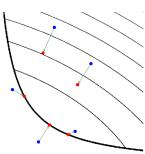

:= $\operatorname{prox}_{1/\rho, f}(v^k)$

Where $\mathbf{prox}_{1/\rho,f}(v^k)$ is referred to as the proximal operator $\mathbf{prox}_{1/\rho,f}: \mathbb{R}^n \to \mathbb{R}^n$ of f with parameter $1/\rho$.

Interpretation of proximal operators

What a prox does: $prox_{\lambda,f}(blue\ points) \rightarrow red\ points$ Two cases:

- three points in the domain of the function stay in the domain and move towards the minimum of the function
- the other two move to the boundary of the domain and towards the minimum of the function

Note that:

- thin black lines:= level curves of a convex function f
- thicker black line := the boundary of its domain
- λ := trade-off parameter between the two terms. What happens if λ is big/small?

Special cases of proximal operators

When *f* is the indicator function:

$$I_C(x) = \begin{cases} 0 & \text{if} \quad x \in C, \\ +\infty & \text{if} \quad x \notin C, \end{cases}$$

where C is a closed nonempty convex set. The proximal operator becomes:

$$\mathbf{prox}_{\lambda,f}(v) := \underset{x}{\operatorname{argmin}} \left(f(x) + \frac{1}{2\lambda} ||x - v||_{2}^{2} \right)$$

$$\iff := \underset{x \in C}{\operatorname{argmin}} \left(f(x) + \frac{1}{2\lambda} ||x - v||_{2}^{2} \right)$$

$$\iff = \underset{x \in C}{\operatorname{argmin}} \left(||x - v||_{2}^{2} \right) = \Pi_{C}(v)$$

Hence the proximal operator of f reduces to Euclidean projection onto C.

...Proximal operators can thus be viewed as generalized projections!

Special cases of proximal operators

When f is the l-1 norm of x: $f(x) = ||x||_1 = \sum_{i=1}^{n} |x_i|$ (non-differentiable). The proximal operator becomes:

$$\mathbf{prox}_{\lambda,f}(v) := \underset{x}{\operatorname{argmin}} \left(||x||_1 + \frac{1}{2\lambda} ||x - v||_2^2 \right)$$

Recall $||x||_2^2 = \sum_i^n x_i^2$, hence the function to minimize is separable w.r.t. each x_i component. Indeed:

$$\operatorname{prox}_{\lambda,f}(v) := \operatorname{argmin}_{x} \left(\sum_{i=1}^{n} \left(|x_{i}| + \frac{1}{2\lambda} (x_{i} - v_{i})^{2} \right) \right)$$

x-minimization splits into *n* independent problems:

$$\begin{split} \left[\textbf{prox}_{\lambda,f}(v) \right]_i &:= \underset{x_i \in \mathbb{R}}{\text{argmin}} \quad |x_i| + \frac{1}{2\lambda} (x_i - v_i)^2 \\ &\iff := \underset{x_i \in \mathbb{R}}{\text{argmin}} \quad \underset{x_i \in \mathbb{R}}{\lambda |x_i|} + \frac{1}{2} (x_i - v_i)^2 \end{split}$$

i.e. given v_i , find the minimizer x_i of the scalar function.

Consider the scalar function:

$$I(x_i) = \frac{\lambda}{2}|x_i| + \frac{1}{2}(x_i - v_i)^2.$$
 (6)

It is convex:

- $|x_i|$ is not differentiable but convex
- $(x_i v_i)^2$ is differentiable and convex

The minimizer of f, denoted as x_i^* , can be obtained by considering the first-order optimality condition. As $|x_i|$ is not differentiable, we use the optimality condition for non-smooth functions (no constraints).

Minimum of a non-smooth function

A point x_i^* is a minimizer of a convex function I if and only if I is subdifferentiable at x_i^* and

$$0 \in \partial I(x_i^*). \tag{7}$$

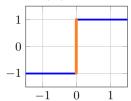

Few subdifferential calculus rules:

• if
$$l(x) = l_1(x) + l_2(x)$$
, then $\partial l(x) = \partial l_1(x) + \partial l_2(x)$

② if I_2 is differentiable, then $\partial I_2(x) = \{\nabla I_2(x)\}$

First-order optimality condition for $I(x_i)$:

① The subdifferential of $|x_i|$ is $sgn(x_i)$ for $x_i \neq 0$ and [-1, 1] for $x_i = 0$:

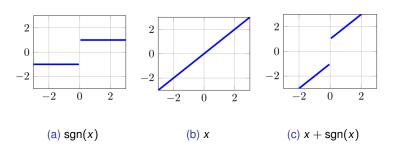

2 The gradient of $\frac{1}{2}(x_i - v_i)^2$ is $(x_i - v_i)$.

Hence (to ease the reading, we consider the case $x_i \neq 0$):

$$0 \in \partial I(x_i^{\star}) \iff 0 \in \lambda \operatorname{sgn}(x_i^{\star}) + (x_i^{\star} - v_i) \iff v_i = x_i^{\star} + \lambda \operatorname{sgn}(x_i^{\star})$$

Let us know express x_i^* as a function of v_i . For ease of notation, we drop the subscript i in the **two** following slides. This can be done by swapping the xv axes of the plot of $v = x + \lambda \text{sgn}(x)$ (or more formally, computing its inverse).

As a simple illustration for the case $\lambda = 1$:

Swapping the axes and including the case $x_i = 0$, we get the soft thresholding operator S:

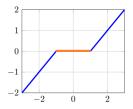

Figure: $S(v) = sgn(v)(|v| - 1)_{+} = sgn(v)max(|v| - 1, 0)$

In general case with threshold λ , we have:

$$S_{\lambda}(v) = \operatorname{sgn}(v) (|v| - \lambda)_{+}^{4}$$
(8)

In MATLAB : sign(v).*(max(abs(v)-lambda,0)); ⁴Equivalent formula is $S_{\lambda}(v) = (v - \lambda)_{+} - (-v - \lambda)_{+}$

Finally, the proximal operator ⁵:

$$\mathbf{prox}_{\lambda,f}(v) := \underset{x}{\operatorname{argmin}} \left(||x||_1 + \frac{1}{2\lambda} ||x - v||_2^2 \right)$$

can be computed by the following update rule:

$$\mathsf{prox}_{\lambda,f}(v) = S_{\lambda}(v)$$

where S_{λ} is the soft thresholding operator applied on ν componentwise:

$$\left[\operatorname{prox}_{\lambda,f}(v)\right]_i = \operatorname{sgn}(v_i)\left(|v_i| - \lambda\right)_+$$

Remark: the proximal operator has been computed in closed form!

⁵**Attention**, we are back to the original notations: $x, v \in \mathbb{R}^n$

Proximal operators: MatLab Toolbox

For further readings, examples of proximal operators and getting access to an open-source MatLab toolbox called Unlocbox dedicated to convex optimization (in particular proximal methods and ADMM), the reader is invited to consult:

► UNLOCBOX - documentation and ► UNLOCBOX - Proximal operators

Prox is related to iterative methods

• When f is differentiable and λ is small: $\mathbf{prox}_{\lambda,f}$ can also be interpreted as a kind of gradient step for the function f (under some assumptions not detailed here):

$$\mathbf{prox}_{\lambda,f} \approx v - \lambda \nabla f(v)$$

This suggests a close connection between proximal operators and gradient methods, more on that in Appendix 2.

 The fixed points of the proximal operator of f are precisely the minimizers of f.In other words:

$$\operatorname{prox}_{\lambda,f}(x^{\star}) = x^{\star} \iff x^{\star} \text{ minimizes } f.$$

- ightarrow close connection between proximal operators and fixed point theory
- \rightarrow proximal algorithms interpreted as solving optimization problems by finding fixed points of appropriate operators.
- More details and demonstrations, see (Parikh and Boyd, 2013)

Smooth objective

desired order over some domain).

f is smooth (function that has continuous derivatives up to some

- for the x-update, can use standard methods for smooth minimization:
 - gradient-based methods, Newton or quasi-Newton,
 - a very good choice would be limited-memory BFGS since it scale to very large problems and the augmentation with a quadratic term puts this method in the best context (rely on smoothness to be efficient).

Constrained convex optimization

Consider ADMM for a generic convex problem:

$$\min_{x} f(x)$$

subject to $x \in C$,

• **ADMM** form: take *g* as the indicator function of the set *C*:

$$\min_{x,z}$$
 $f(x) + g(z)$
subject to $x - z = 0$,

• Build the augmented Lagrangian (scaled form):

$$L_{\rho}(x,z,y) = f(x) + g(z) + \frac{\rho}{2}||x-z+u||_{2}^{2}$$

Constrained convex optimization

By combining the special cases of proximal operators presented previously, we get the **ADMM** steps (equivalent to Douglas-Rachford, here):

$$z^{k+1} := \Pi_C(x^{k+1} + u^k)$$
 %z-minimization

$$u^{k+1} := u^k + (x^{k+1} - z^{k+1})$$
 %dual update

Alternating projections, revisited

Consider finding a point x in intersection of (simple) convex sets C and \mathcal{D} .

• Let us formulate this as an optimization problem:

• **ADMM** form: take f, g as the indicators function of the set C and \mathcal{D} resp.:

$$\min_{x,z} f(x) + g(z)$$

subject to $x - z = 0$,

Alternating projections, revisited

By combining the special cases of proximal operators presented previously, we get the **ADMM** steps:

$$z^{k+1} := \Pi_{\mathcal{D}}(x^{k+1} + u^k)$$
 %z-minimization

$$u^{k+1} := u^k + (x^{k+1} - z^{k+1})$$
 %dual update

This is like the classical alternating projections method, but now with a dual variable u (much more efficient).

Least Absolute Shrinkage and Selection Operator (Lasso)

• Given $y \in \mathbb{R}^n$, $X \in \mathbb{R}^{n \times p}$, we are interested in solving:

$$\min_{\beta \in \mathbb{R}^p} \quad \frac{1}{2} ||y - X\beta||_2^2 + \lambda ||\beta||_1 \tag{9}$$

where $\lambda \ge 0$ is a given regularization parameter and $|\beta|_1 = \sum_i^n |x_i|_1$ is the L_1 -norm of β .

- This problem is referred to as the **Lasso** problem.
- ADMM form:

$$\min_{\beta,\alpha\in\mathbb{R}^p} \frac{1}{2} ||y - X\beta||_2^2 + \lambda ||\alpha||_1$$

subject to $\beta - \alpha = 0$,

Lasso

• ADMM steps:

- $u^{k+1} := u^k + (\beta^{k+1} \alpha^{k+1})$ %dual update

Lasso: Steps 1 and 2

Step 1

 $f(x) = \frac{1}{2}||y - X\beta||_2^2$ is a quadratic, we obtain

$$\beta^{k+1} := (X^T X + \rho I)^{-1} (\rho v^k + X^T y)$$

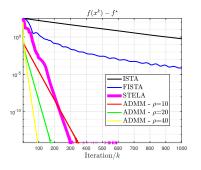

where $v^k = \alpha^k - u^k$ and $X^TX + \rho I$ is always invertible, regardless of X. If we compute a factorization (say Cholesky) in $O(p^3)$ flops, then each β update takes $O(p^2)$ flops (complexity of forward/backward substitution).

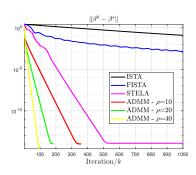

Step 2

The z-update corresponds to the proximal operator associated to the *l*-1 norm of parameter $\frac{\lambda}{\rho}$, therefore:

$$\alpha^{k+1} := \mathbf{prox}_{\lambda/\rho, \|.\|_1} (\beta^{k+1} + u^k)$$
$$= S_{\lambda/\rho} (\beta^{k+1} + u^k)$$

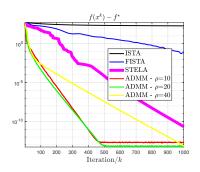

Comparison of various algorithms: instances with n = 1000, p = 100

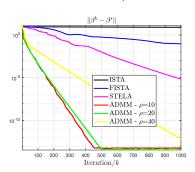

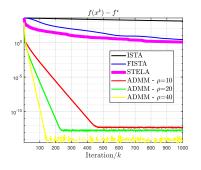

► MatLab Code

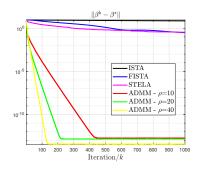

Comparison of various algorithms: instances with n = 100, p = 1000

Comparison of various algorithms: instances with n = 1000, p = 1000

Remark: **STELA** algorithm (Yang and Pesavento, 2017) seems more sensible to initialization than other methods. Therefore random and various initializations should be done to compare more accurately and fairly the algorithms.

Remarks:

- Other methods exist for solving Lasso problem such as Coordinate descent-based methods that showed high effectiveness (for small size problems), see (Tibshirani, 2015) - page 11 for a numerical comparison.
- The proper choice of λ is crucial for good performance of this algorithm, but this is not an easy task. Unfortunately we are not in the place here to give you a rule of thumb what to do, since it highly depends on the application at hand. Again, consult (Beck et al 2009) for any further considerations of this matter.

Generalized lasso, revisited

• Given the usual $y \in \mathbb{R}^n$, $X \in \mathbb{R}^{n \times p}$ and an additional $D \in \mathbb{R}^{m \times p}$, the *generalized lasso* problem solves:

$$\min_{\beta \in \mathbb{R}^p} \quad \frac{1}{2} ||y - X\beta||_2^2 + \lambda ||D\beta||_1 \tag{10}$$

• The generalized lasso is computationally harder than the lasso (D = I).

ADMM form:

$$\begin{split} & \min_{\beta \in \mathbb{R}^p, \alpha \in \mathbb{R}^m} & & \frac{1}{2} \|y - X\beta\|_2^2 + \lambda \|\alpha\|_1 \\ & \text{subject to} & & D\beta - \alpha = 0, \end{split}$$

Generalized lasso, revisited

- However, **ADMM** delivers a simple algorithm:

- $u^{k+1} := u^k + (D\beta^{k+1} \alpha^{k+1})$ %dual update

Intermediate steps let as an exercise!

Low rank approximation of a matrix

Disclaimer: before we present examples of LOw-RAnk Matrix APproximations (LORAMAP ⁶) solved by using **ADMM**:

- we recall fundamental principles and tools from linear algebra as the notions of the rank and the Singular Value Decomposition (SVD) of a matrix A ∈ R^{m×n},
- we recall that SVD can be used to find to best rank-r approximation of a matrix, w.r.t. any unitarily invariant norm (and without any additional constraints),
- we briefly introduce the Matrix Rank Minimization problems and the general Low Rank Regularization framework,
- we present the link between the nuclear norm and the rank of a matrix, that is nuclear norm is the convex envelope (tightest convex relaxation) of the rank (within the unit ball).

⁶Partial reproduction of the name of Nicolas Gillis PERC

LORAMAP: basics from linear algebra

Rank and basic properties:

Rank definition

For field \mathbb{F} , let $A \in \mathbb{F}^{m \times n}$. Then

$$rank(A) := dim(range(A))$$

where range(A) denotes the linear space spanned by the columns of A.

For simplicity, $\mathbb{F} = \mathbb{R}$ throughout the lecture and often $m \ge n$. Lemma:

- $rank(A) = rank(A^T)$ (the dimension of the column space of the matrix is equal to the dimension of its row space)
- $\operatorname{rank}(PAQ) = \operatorname{rank}(A)$ for any invertible matrices $P \in \mathbb{R}^{m \times m}$ and $Q \in \mathbb{R}^{n \times n}$.
- $\operatorname{rank}\begin{pmatrix} A_{11} & A_{12} \\ 0 & A_{22} \end{pmatrix} = \operatorname{rank}(A_{11}) + \operatorname{rank}(A_{22}).$

LORAMAP: basics from linear algebra

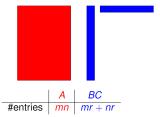

Rank and matrix factorizations:

Lemma

A matrix $A \in \mathbb{R}^{m \times n}$ of rank r admits a factorization of the form:

$$A = BC, B \in \mathbb{R}^{m \times r}, C \in \mathbb{R}^{r \times n}.$$

We say that *A* has low rank if rank(A) \ll min(m, n). Illustration of low-rank factorization:

- Generically (and in most applications), A has full rank.
 - Aim instead at approximating A by a low-rank matrix.

LORAMAP: SVD

Fundamental tool: The Singular Value Decomposition (SVD)

Theorem

Let $A \in \mathbb{R}^{m \times n}$ with $m \ge n$, then there are orthogonal matrices $U \in \mathbb{R}^{m \times m}$ and $V \in \mathbb{R}^{n \times n}$ such that:

$$A = U\Sigma V^T \text{ with } \Sigma = \begin{bmatrix} \sigma_1 & & & \\ & \ddots & & \\ & & \sigma_n \end{bmatrix} \in \mathbb{R}^{m \times n}$$
$$0_{(m-n) \times n}$$

and $\sigma_1 \geq \sigma_2 \geq ... \geq \sigma_n \geq 0$.

where:

- $\sigma_1, ..., \sigma_n$ are called the singular values,
- $u_1, ..., u_n$ are called the left singular vectors,
- $v_1, ..., v_n$ are called the right singular vectors,

•
$$Av_i = \sigma_i u_i$$
, $A^T u_i = \sigma_i v_i$, $i = 1, ..., n$.

LORAMAP: SVD

Very basic properties of SVD

- r = rank(A) is number of nonzero singular values of A, i.e., the rank of a matrix A is the l-0 norm of the vector composed of the singular values of A. (note that l-0 norm is actually not a norm since $||\alpha x|| = |\alpha|||x||$ does not hold for all α .)
- $kernel(A) = span^7(v_{r+1}, ..., v_n),$
- range(A) = span($u_1, ..., u_r$),

⁷the set of all finite linear combinations

LORAMAP: SVD

Norms: Spectral and Frobenius norm

- Given SVD $A = U\Sigma V^T$, one defines:
 - Spectral norm: $||A||_2 = \sigma_1$,
 - Frobenius norm:

$$||A||_{F} = \sqrt{\langle A, A \rangle}$$

$$= \sqrt{\text{Tr}(A^{T}A)} = \sqrt{\sum_{ij} |A_{ij}|^{2}} = \sqrt{\sigma_{1}^{2} + ... + \sigma_{n}^{2}}$$

- Basic properties:
 - $||A||_2 = \max(||Av||_2|||v||_2 = 1)$,
 - ||.||2 and ||.||F are both unitarily invariant, that is

$$||QAP||_2 = ||A||_2, ||QAP||_F = ||A||_F$$
 (11)

for any orthogonal matrices Q and P.

LORAMAP: best rank-r approximation

Now, let us introduce the optimal low-rank approximation problem in $\mathbb{R}^{m \times n}$, which is formulated as follows:

Problem 1

Let $A \in \mathbb{R}^{m \times n}$ and $1 \le r \le \min(m, n)$, find $X^* \in \mathbb{R}^{m \times n}$ with rank $(X^*) \le r$ such that

$$\min_{\mathsf{rank}(X) \le r} \|A - X\| = \|A - X^*\|$$

for some given operator norm ||.||.

LORAMAP: best rank-r approximation

The problem has been solved by Schmidt and was generalized by Mirsky to unitarily invariant norms:

Proposition 1

Given $A \in \mathbb{R}^{m \times n}$ and $1 \le r \le \min(m, n)$, then

$$\min_{\mathsf{rank}(X) \leq r} \lVert A - X \rVert = \lVert \mathsf{diag}(\sigma_{r+1}(A), ..., \sigma_{\mathsf{min}(m,n)}(A)) \rVert$$

for any unitarily invariant norm ||.||.

Hence, if an SVD of A is given by $A = \sum_{i}^{\min(m,n)} \sigma_{i} u_{i} v_{i}^{T}$, then an optimal solution is $X^{*} = \sum_{i}^{r} \sigma_{i} u_{i} v_{i}^{T}$. This solution may not be unique if the norm does not depend on all singular values or if $\sigma_{r}(A) = \sigma_{r+1}(A)$. Nevertheless, if the chosen norm is the Frobenius-norm and $\sigma_{r}(A) \neq \sigma_{r+1}(A)$, then there is a unique solution.

LORAMAP: best rank-r approximation, application

Image Processing: A is a gray-scale image, we display rank-r approximations for r = 2, ..., 25.

LORAMAP: best rank-r approximation, application

Remark: Rank-20 approximation already gives a good approximation of the original image. It implies that

- The main information is " contained" within the first singular values,
- a low-rank approximation makes sense, for compression purpose for instance.

Matrix Rank Minimization problems (RMP)

Consider:

- As explained previously: the rank has various definition, one of them is the *I*-0 norm of the singular values of X: let σ be the vector holding the singular values of X, then: $\operatorname{rank}(X) = ||\sigma||_0$,
- Mainly due to the combinatorial nature of the *I*-0 norm⁸: the problem RMP is NP-hard. However, it has a trivial solution: X equal to zero matrix.

⁸*I*-0 norm minimization problem are well known to be NP-hard. As RMP is at least as hard as *I*-0-norm minimization problem, so RMP is (at least) NP-hard.

RMP with constraint: CRMP

• The Constrained RMP (CRMP) is:

$$\min_{X \in \mathbb{R}^{m \times n}} \operatorname{rank}(X)
\text{subject to} \quad h(X) = 0,$$
(12)

 Let us consider a special case of (12) where h(X) are affine operators of X:

$$\min_{X \in \mathbb{R}^{m \times n}} \operatorname{rank}(X)
\text{subject to} \quad A(X) = b,$$
(13)

where $A: \mathbb{R}^{m \times n} \to \mathbb{R}^d$ is an affine operator and $A: \mathbb{R}^d$ is a vector. Problem (13) is referred to as Affine RMP (ARMP).

- Problem (13) has interesting structure to be analyzed and covers lots of applications.
- Note that the affine constraint is convex, and the problem is NP-hard because of the rank.

ARMP and related problems

P-ARMP or R-ARMP:

$$\min_{X \in \mathbb{R}^{m \times n}} \quad \operatorname{rank}(X) + \lambda \operatorname{dist}(A(X), b) \tag{14}$$

- cast ARMP in the penalty/regularized form by adding the constraint into the objective function with the penalty weight $\lambda > 0$
- unconstrained problem
- 3 dist() function that measures the distance between A(X) and b.
- Particular case: $dist(A(X), b) = ||A(X) b||_F$
- R-ARMP considered in practice when we assume additive noise model:

$$A(X) = b + \varepsilon$$

where ε is a random variable that models the noise. The noise statistics has to been chosen appropriately w.r.t. the applications at hand.

General framework: Low Rank Regularization

In the last decade, several attempts have been made to unify these LORAMAP's problems within a unified framework. Let us mention here the Low Rank Regularization framework which considers the following general formulation:

Consider:

$$\min_{X \in \mathbb{R}^{m \times n}} \operatorname{rank}(X) + \lambda L(X)$$
subject to $X \in C$, (15)

where:

- \bigcirc L(X) represents some general regularization on X,
- 2 C represents the constraints over X,
- Still NP-hard problem.

In the following slides, we present some tools to replace the rank function by some easier object to deal with.

- Rank function: $\operatorname{rank}(A) : \mathbb{R}^{m \times n} \to \mathbb{N}$, can be defined as the *I*-0 norm of the vector of the singlar values of A.
- Nuclear norm (or less standard the trace norm):

$$||A||_* := \sum_{i}^{\min(m,n)} \sigma_i(A),$$

the sum of the singular values of A. Since the singular values are nonnegative by definition, the nuclear norm is equivalent to the l-1 norm of the vector of the singular values of A.

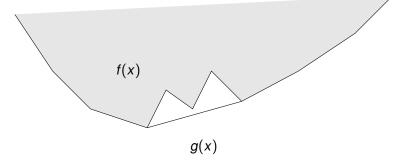

The concept of convex envelope:

Given a function $f : \mathbb{E} \to \mathbb{R}$, a function g is called the convex envelope of f if and only if g is convex and

$$g(x) \le f(x), \ \forall x \in \mathbb{E}$$

i.e., g is a convex lower bound on our original function.

Illustration:

Theorem (Fazel 2002)

For $f(X) = \operatorname{rank}(X)$ over the set

$$\mathcal{S} := \{X \in \mathbb{R}^{m \times n} |||X||_2 \le 1\}$$

the convex envelope of f is the nuclear norm $||X||_*$.

- The theorem only applies to those X inside the unit ball. It tells
 nothing if X is outside the unit ball. In fact, if X is outside the unit ball,
 the output of the convex envelope will be at ∞.
- If we have $S' := \{X \in \mathbb{R}^{m \times n} ||X||_2 \le M\}$, we can do a scaling to reuse the theorem : in this case the convex envelope of f on S' will be $1/M||X||_*$ for M > 0.
- The tool to prove the theorem is basically the convex conjugate, more particularly show that the biconjugate of the rank, that is $(\operatorname{rank}(X))^{**}$ is the nuclear norm of X.

As a simple and intuitive illustration: consider $\mathbb{E}=\mathbb{R}^2$ and try to find the convex envelope of the following subset:

$$C = \{x \in \mathbb{E} | ||x||_0 \le 1, ||x||_2 \le 1\}$$

Hint: Draw C and find the convex hull (the set of all convex combinations of every pair of points) of C, corresponds exactly to the I-1 ball and is minimal by definition of convex hull.

Note that if we allow k non zero elements, this illustration is not valid anymore.

Interest for the following: replace the rank by the its convex relaxation (or convex envelope); the nuclear norm.

Sparse low rank decomposition: Context

• Motivation: Given a large data matrix $M \in \mathbb{R}^{m \times n}$, and know that it may be decomposed as (Candes 2011):

$$M = L_0 + S_0$$

where L_0 has low rank and S_0 is sparse; here, both components are of arbitrary magnitude.

- We do not know:
 - \bigcirc low-dimensional column and row space of L_0 , neither their dimension,
 - 2 the locations of the nonzero entries of S_0 , not even how many there are.
- Question: Can we hope to recover the low-rank and sparse components both accurately (perhaps even exactly) and efficiently? (Candes 2011)

Sparse low rank decomposition: Possible formulation

Different formulations:

Classical Principal Component Analysis (PCA):

$$\min_{\operatorname{rank}(L) \leq r} ||M - L||$$

Advantage: can be efficiently solved via the singular value decomposition (SVD) and enjoys a number of optimality properties when the noise N_0 is small and i.i.d. Gaussian.

Drawback: brittleness with respect to grossly corrupted observations often puts its validity in jeopardy ⁹.

Gross errors are now ubiquitous in modern applications such as image processing, web data analysis, and bioinformatics, where some measurements may be arbitrarily corrupted

 $^{^{9}}$ a single grossly corrupted entry in M could render the estimated arbitrarily far from the true L_{0} .

Sparse low rank decomposition: Possible formulation

Different formulations (next):

(one possible) Robust PCA:

$$\min_{\substack{L,S\in\mathbb{R}^{m\times n}}} \operatorname{rank}(L) + \lambda ||S||_0$$
 subject to $L+S=M$,

Advantage: the entries in S_0 can have arbitrarily large magnitude, and their support is assumed to be sparse but unknown and motivated by a different set of applications: Video Surveillance, Face Recognition, etc.

Drawback: NP-hard and (almost) numerically intractable.

Sparse low rank decomposition: (Candes et al 2011) formulation

(Candes et al 2011) showed that the problem can be solved by tractable convex optimization:

$$\min_{L,S\in\mathbb{R}^{m\times n}} \quad \|L\|_* + \lambda \|S\|_1$$
 subject to $L+S=M,$

Main relaxation tool: I-0 norm replaced by I-1 norm

- Under weak assumptions¹⁰, (17) exactly recovers the low-rank L_0 and the sparse S_0 .
- It has been showed in (Chandrasekaran et al 2011) and (Wright et al 2009) that (17) and (16) are equivalent with high probability.

 $^{^{-10}}$ provided that L_0 is sufficiently low-rank and S_0 is sufficiently sparse comparing to the matrix size

Sparse low rank decomposition: ADMM

Note that (17) is already in **ADMM** form.

• Build the augmented Lagrangian (scaled form):

$$L_{\rho}(L, S, U) = ||L||_{*} + \lambda ||S||_{1} + \frac{\rho}{2} ||L + S - M + U||_{F}^{2}$$

- ADMM steps:

- $U^{k+1} := U^k + (L^{k+1} + S^{k+1} M)$ %dual update

Sparse low rank decomposition: ADMM

Remarks

- Step 1: the *L*-update corresponds to the proximal operator associated to the nuclear norm of parameter $\frac{1}{\rho}$ that will be derived in the next slides.
- ② Step 2: the S-update corresponds to the proximal operator associated to the *I*-1 norm of parameter $\frac{\lambda}{\rho}$ derived previously.

Sparse low rank decomposition: Singular Value Thresholding operator

In these slides we give the closed-form expression for the proximal operator associated to the nuclear norm of parameter $\frac{1}{a}$:

$$\mathbf{prox}_{1/\rho, \|\cdot\|_{*}}(W) := \underset{L}{\operatorname{argmin}} \left(\|L\|_{*} + \frac{\rho}{2} \|L - W\|_{F}^{2} \right)$$
$$:= \operatorname{SVT}_{1/\rho}(W) = U[\Sigma - \frac{1}{\rho}]_{+} V^{T}$$
(18)

where *I* is the identity matrix of appropriate size, W = -S + M - U, $U\Sigma V^T = W$ (SVD of *W*) and $[.]_+ = \max(., 0)$.

The operator $SVT_{1/\rho}$ is called the Singular Value Thresholding operator (SVT).

What does SVT?

- **1** Perform SVD on W and get $U\Sigma V^T$
- ② Subtract all the diagonal value of Σ by $1/\rho$, denoted $\Sigma \frac{1}{\rho}$
- **3** Replace negative value in $\Sigma \frac{1}{\rho}$ by zero, denoted $[\Sigma \frac{1}{\rho}]_+$

Showing that the $\mathbf{prox}_{1/\rho,\|.\|.\|_*}$ is equal to the $\mathsf{SVT}_{1/\rho}$ operator can be done by using sub-differential theory. Here we present a shorter proof based on the von Neumann trace inequality:

$$\operatorname{Tr}(X^T Y) \le \sum_i \sigma_i(X) \sigma_i(Y)$$
 (19)

The equality holds X and Y share the same left and right singular vectors.

First we have:

$$\frac{1}{2} \|L - W\|_F^2 = \frac{1}{2} \|L\|_F^2 - \text{Tr}(L^T W) + \frac{1}{2} \|W\|_F^2
\ge \frac{1}{2} \left(\sum_i \sigma_i^2(L) - 2\sigma_i(L)\sigma_i(W) + \sum_i \sigma_i^2(W) \right)
= \frac{1}{2} \sum_i (\sigma_i(L) - \sigma_i(W))^2$$
(20)

Assume that L and W share the same left and right singular vectors, let us inject (20) in (18):

$$\operatorname{prox}_{1/\rho, \|\cdot\|_{*}}(W) := \underset{L}{\operatorname{argmin}} \left(\|L\|_{*} + \frac{\rho}{2} \|L - W\|_{F}^{2} \right)$$

$$:= \underset{L}{\operatorname{argmin}} \left(\frac{1}{\rho} \sum_{i} \sigma_{i}(L) + \frac{1}{2} \sum_{i} \left(\sigma_{i}(L) - \sigma_{i}(W) \right)^{2} \right) \quad (21)$$

$$= \underset{L}{\operatorname{argmin}} \sum_{i} \left(\frac{1}{\rho} \sigma_{i}(L) + \frac{1}{2} \left(\sigma_{i}(L) - \sigma_{i}(W) \right)^{2} \right)$$

Equation (21) implies that:

$$\sigma_{i}\left(\operatorname{\mathbf{prox}}_{1/\rho,\|.\|_{*}}(W)\right) := \underset{\sigma_{i}(L) \geq 0}{\operatorname{argmin}} \left(\frac{1}{\rho}\sigma_{i}(L) + \frac{1}{2}\left(\sigma_{i}(L) - \sigma_{i}(W)\right)^{2}\right) \tag{22}$$

which can solved in parallel and in closed form by using the soft thresholding operator.

Equation (22) finally becomes:

$$\sigma_{i}\left(\operatorname{prox}_{1/\rho,\|.\|_{*}}(W)\right) := S_{1/\rho}\left(\sigma_{i}\left(W\right)\right)$$

$$= \operatorname{sgn}\left(\sigma_{i}\left(W\right)\right)\left(|\sigma_{i}\left(W\right)| - \frac{1}{\rho}\right)_{+}$$

$$= \left(\sigma_{i}\left(W\right) - \frac{1}{\rho}\right)_{+}$$
(23)

since $\sigma_i \ge 0$ by definition.

Finally, since L and W share the same left and right singular vectors, $\mathbf{prox}_{1/\rho,\|.\|_*}(W)$ also does, therefore:

$$\operatorname{\mathsf{prox}}_{1/\rho,\|.\|_*}(W) := U[\Sigma - \frac{I}{\rho}]_+ V^T$$

$$= \operatorname{\mathsf{SVT}}_{1/\rho}(W)$$
(24)

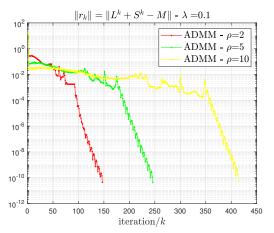

Sparse low rank decomposition: ADMM

- ADMM steps are:

- 3 $U^{k+1} := U^k + (L^{k+1} + S^{k+1} M)$ %dual update

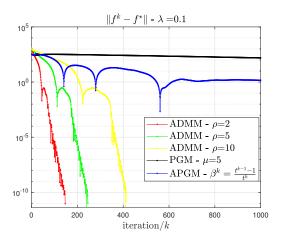

Sparse low rank decomposition: numerical experiments

Comparison of various algorithms: instance with n = 100, m = 100, rank(L0) = 5, $\lambda = 1/\sqrt{m}$:

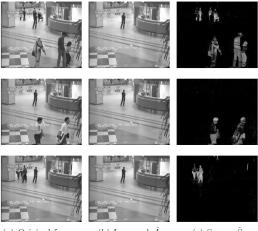

Sparse low rank decomposition: numerical experiments

By choosing (very carefully) the **ADMM** parameter ρ and the penalty weight λ as suggested by (Candes et al 2011), **ADMM** algorithm is able to recover L_0 and S_0 with high accuracy (as the rank). **APGM** gives good results as well.

Sparse low rank decomposition: Example from (Candes et al 2011)

(a) Original frames

(b) Low-rank \hat{L}

(c) Sparse \hat{S}

Sparse low rank decomposition: Example from (Candes et al 2011)

Remarks:

- Given a sequence of surveillance video frames, we often need to identify activities that stand out from the background.
- we stack the video frames as columns of a matrix M.
- the low-rank component L₀ naturally corresponds to the stationary background,
- the sparse component S_0 captures the moving objects in the foreground.

Low-rank Tensor Decomposition for Incomplete data I

 Decomposition of a tensor y with missing elements can be formulated as

$$\min \quad \|\mathcal{W} \circledast (\mathcal{Y} - \hat{\mathcal{Y}})\|_F^2 \tag{25}$$

where ${\cal W}$ is a binary weight tensor, 1s for observed entries and 0s for the missing.

 \bullet The approximated tensor ${\bf y}$ can be in a low-rank tensor format, e.g., CPD, TKD, TT, TC.

Low-rank Tensor Decomposition for Incomplete data II

 \bullet Different low-rank models demand algorithms to update parameters of $\hat{\mathcal{Y}}$

For example,
$$\hat{\mathcal{Y}} = \mathbf{G} \times_1 \mathbf{U}_1 \times_2 \mathbf{U}_2 \times_3 \mathbf{U}_3$$
, in order to update \mathbf{U}_1

min
$$\|\operatorname{diag}(\operatorname{vec}(\mathcal{W}))(\operatorname{vec}(\mathcal{Y}) - ((\mathbf{U}_3 \otimes \mathbf{U}_2)\mathbf{G}_{(1)}^T \otimes \mathbf{I}_I)\operatorname{vec}(\mathbf{U}_1))\|_F^2$$
 (26)

then

$$\text{vec}\big(\boldsymbol{U}_1^{\star}\big) = (\boldsymbol{Z}^{T} \operatorname{diag}(\text{vec}(\mathcal{W})^2)\boldsymbol{Z})^{-1} \ \boldsymbol{Z}^{T} \operatorname{diag}(\text{vec}(\mathcal{W})^2) \operatorname{vec}(\mathcal{Y})$$

 Best algorithms for ordinary tensor decompositions cannot be used, e.g., LM for CPD, HOOI for TKD, TT-SVD for TT.

Low-rank Tensor Decomposition for Incomplete data III

• Optimization problem for low-rank constrained tensor decomposition

min
$$\frac{1}{2}\|\mathcal{W}\circledast(\mathcal{Y}-\mathcal{X})\|_F^2+i_{LR}(\mathcal{X})$$
 (27)

where $i_{LR}(\mathfrak{X})$ is the indicator function of a low-rank tensor model, 0 if \mathfrak{X} is represented in the LR format, otherwise ∞ .

ADMM algorithm

min
$$\frac{1}{2} \| \mathcal{W} \circledast (\mathcal{Y} - \mathcal{X}) \|_F^2 + i_{LR}(\mathcal{X})$$
 (28)

s.t.
$$\mathfrak{X}=\mathfrak{Z}$$
 (29)

Write the augmented Lagrangian function

$$\mathcal{L}(\mathcal{X},\mathcal{Z},\mathcal{T}) = \frac{1}{2} ||\mathcal{W} \circledast (\mathcal{Y} - \mathcal{X})||_F^2 + i_{LR}(\mathcal{Z}) + \frac{\lambda}{2} (||\mathcal{X} - \mathcal{Z} - \mathcal{T}||_F^2 - ||\mathcal{T}||_F^2) (3e^{-\frac{1}{2}} ||\mathcal{X} - \mathcal{Z} - \mathcal{T}||_F^2 - ||\mathcal{T}||_F^2)$$

where $\lambda > 0$.

Low-rank Tensor Decomposition for Incomplete data IV

Update parameters

$$\mathfrak{X}^{(k+1)} = \arg\min \frac{1}{2} \| \mathcal{W} \otimes (\mathcal{Y} - \mathcal{X}) \|_F^2 + \frac{\lambda}{2} \| \mathcal{X} - \mathcal{Z}^{(k)} - \mathcal{T}^{(k)} \|_F^2 (31)$$

$$\mathfrak{Z}^{(k+1)} = \arg\min i_{LR}(\mathfrak{Z}) + \frac{\lambda}{2} \| \mathcal{X}^{(k+1)} - \mathfrak{Z} - \mathcal{T}^{(k)} \|_F^2 \qquad (32)$$

$$\mathfrak{T}^{(k+1)} = \mathfrak{T}^{(k+1)} + \mathfrak{Z}^{(k+1)} - \mathfrak{X}^{(k+1)} \qquad (33)$$

• Update \mathfrak{X} :

$$\mathfrak{X} = \frac{1}{1+\lambda} \mathcal{W} \circledast (\mathcal{Y} + \lambda(\mathcal{Z}^{(k)} + \mathcal{T}^{(k)})) + (1-\mathcal{W}) \circledast (\mathcal{Z}^{(k)} + \mathcal{T}^{(k)})$$
(34)

Update 2

$$\mathfrak{Z}^{(k+1)} = \operatorname{LR} \operatorname{approximation}(\mathfrak{X}^{(k+1)} - \mathfrak{T}^{(k)})$$
 (35)

Low-rank Tensor Decomposition for Incomplete data V

Example

Optimal Ranks for Tucker decomposition I

- ullet Approximate a tensor ${\mathcal Y}$ by a tensor ${\mathcal X}$ in the Tucker format.
- ullet Finding optimal multilinear ranks is equivalent to seeking ${\mathfrak X}$ such that its mode-n ranks is minimal

min
$$\alpha_1 \| \mathbf{X}_{(1)} \|_* + \alpha_2 \| \mathbf{X}_{(2)} \|_* + \alpha_3 \| \mathbf{X}_{(3)} \|_*$$
 (36)

s.t.
$$\|\mathcal{Y} - \mathcal{X}\|_F^2 \le \delta^2$$
 (37)

• For the model with the smallest number of parameters

min
$$||X_{(1)}||_* + J||X_{(2)}||_* + K||X_{(3)}||_* + ||X_{(1)}||_*||X_{(2)}||_*||X_{(3)}||_*$$

s.t. $||Y - X||_F^2 \le \delta^2$

Optimal Ranks for Tucker decomposition II

•

min
$$\alpha_1 \|\mathbf{Z}_1\|_* + \alpha_2 \|\mathbf{Z}_2\|_* + \alpha_3 \|\mathbf{Z}_3\|_*$$
 (38)

s.t.
$$\|\mathcal{Y} - \mathcal{X}\|_F^2 \le \delta^2 \tag{39}$$

$$\mathfrak{X}_{(1)} = \mathbf{Z}_1 \tag{40}$$

$$\mathfrak{X}_{(2)} = \mathbf{Z}_2 \tag{41}$$

$$\mathfrak{X}_{(3)} = \mathbf{Z}_3 \tag{42}$$

Augmented Lagrangian function

$$\mathcal{L}(\mathbf{X}, \mathbf{Z}_{1}, \mathbf{Z}_{2}, \mathbf{Z}_{3}) = \alpha_{1} \|\mathbf{Z}_{1}\|_{*} + \alpha_{2} \|\mathbf{Z}_{2}\|_{*} + \alpha_{3} \|\mathbf{Z}_{3}\|_{*} + i_{D}(\mathbf{X})$$

$$+ \frac{\lambda}{2} (\|\mathbf{X}_{(1)} - \mathbf{Z}_{1} - \mathbf{T}_{1}\|_{F}^{2} + \|\mathbf{X}_{(2)} - \mathbf{Z}_{2} - \mathbf{T}_{2}\|_{F}^{2} + \|\mathbf{X}_{(3)} - \mathbf{Z}_{3} - \mathbf{T}_{3}\|_{F}^{2} - \mathbf{T}_{3} \|\mathbf{Z}_{3}\|_{F}^{2} + \|\mathbf{X}_{3}\|_{F}^{2} +$$

Optimal Ranks for Tucker decomposition III

Update rules

$$\mathbf{Z}_{1}^{(k+1)} = \arg \min \alpha_{1} \|\mathbf{Z}_{1}\|_{*} + \frac{\lambda}{2} \|\mathbf{X}_{(1)}^{(k)} - \mathbf{Z}_{1} - \mathbf{T}_{1}^{(k)}\|_{F}^{2} \qquad (43)$$

$$\mathbf{Z}_{2}^{(k+1)} = \arg \min \alpha_{2} \|\mathbf{Z}_{2}\|_{*} + \frac{\lambda}{2} \|\mathbf{X}_{(2)}^{(k)} - \mathbf{Z}_{2} - \mathbf{T}_{2}^{(k)}\|_{F}^{2} \qquad (44)$$

$$\mathbf{Z}_{3}^{(k+1)} = \arg \min \alpha_{3} \|\mathbf{Z}_{3}\|_{*} + \frac{\lambda}{2} \|\mathbf{X}_{(3)}^{(k)} - \mathbf{Z}_{3} - \mathbf{T}_{3}^{(k)}\|_{F}^{2} \qquad (45)$$

$$\mathbf{X}^{(k+1)} = \arg \min i_{D}(\mathbf{X}) + \frac{\lambda}{2} (\|\mathbf{X}_{(1)} - \mathbf{Z}_{1} - \mathbf{T}_{1}\|_{F}^{2} + \|\mathbf{X}_{(2)} - \mathbf{Z}_{2} - \mathbf{T}_{2}\|_{F}^{2} + \|\mathbf{X}_{(3)} - \mathbf{Z}_{3} - \mathbf{T}_{3}\|_{F}^{2}) \qquad (46)$$

$$\mathbf{T}_{n}^{(k+1)} = \mathbf{T}_{n}^{(k)} + \mathbf{Z}_{n}^{(k+1)} - \mathbf{X}_{(n)}^{(k+1)} \qquad (47)$$

(47)

Optimal Ranks for Tucker decomposition IV

Update Z₁, Z₂ and Z₃

$$\mathbf{Z}_{1}^{(k+1)} = \arg \min \alpha_{1} \|\mathbf{Z}_{1}\|_{*} + \frac{\lambda}{2} \|\mathbf{X}_{(1)}^{(k)} - \mathbf{Z}_{1} - \mathbf{T}_{1}^{(k)}\|_{F}^{2}$$

$$= \operatorname{SVT}_{\frac{\alpha_{1}}{\lambda}} (\mathbf{X}_{(1)}^{(k)} - \mathbf{T}_{1}^{(k)})$$
(48)

$$\mathbf{Z}_{2}^{(k+1)} = \text{SVT}_{\frac{a_{2}}{\lambda}}(\mathfrak{X}_{(2)}^{(k)} - \mathbf{T}_{2}^{(k)})$$
 (49)

$$\mathbf{Z}_{3}^{(k+1)} = \text{SVT}_{\frac{\alpha_{3}}{l}}(\mathfrak{X}_{(3)}^{(k)} - \mathbf{T}_{3}^{(k)})$$
 (50)

Optimal Ranks for Tucker decomposition V

• Update \mathfrak{X} : solve the constrained minimization problem

$$\begin{split} & \text{min} & \quad \|\boldsymbol{\mathcal{X}}_{(1)} - \mathbf{Z}_1 - \mathbf{T}_1\|_F^2 + \|\boldsymbol{\mathcal{X}}_{(2)} - \mathbf{Z}_2 - \mathbf{T}_2\|_F^2 + \|\boldsymbol{\mathcal{X}}_{(3)} - \mathbf{Z}_3 - \mathbf{T}_3\|_F^2 \\ & \text{s.t} & \quad \|\boldsymbol{\mathcal{Y}} - \boldsymbol{\mathcal{X}}\|_F^2 \leq \delta^2 \end{split}$$

or

where $[\mathcal{V}_1]_{(1)} = \mathbf{Z}_1 + \mathbf{T}_1$, $[\mathcal{V}_2]_{(2)} = \mathbf{Z}_2 + \mathbf{T}_2$, and $[\mathcal{V}_3]_{(3)} = \mathbf{Z}_3 + \mathbf{T}_3$. Optimal solution \mathfrak{X}^{\star}

$$\mathfrak{X}^{\star} = \mathfrak{Y} - \min(1, \frac{\delta}{\|\mathfrak{Y} - \bar{\mathcal{V}}\|_{F}})(\mathfrak{Y} - \bar{\mathcal{V}})$$
 (51)

where $\bar{\mathcal{V}}=\frac{1}{3}(\mathcal{V}_1+\mathcal{V}_2+\mathcal{V}_3).$

Optimal Ranks for TT decomposition I

- Approximate a tensor \mathcal{Y} by a tensor \mathcal{X} in the TT format.
- ullet Finding optimal multilinear ranks is equivalent to seeking ${\mathfrak X}$ such that its mode-n ranks is minimal

min
$$\sum_{n=1}^{N} \alpha_n || \mathcal{X}_{(< n)} ||_*$$
 (52)
s.t.
$$|| \mathcal{Y} - \mathcal{X} ||_F^2 \le \delta^2$$
 (53)

$$\text{s.t.} \qquad \|\mathcal{Y} - \mathcal{X}\|_F^2 \le \delta^2 \tag{53}$$

where $\mathfrak{X}_{(< n)}$ is mode-(1 : n) unfolding of \mathfrak{X} , of size $(I_1I_2\cdots I_n)\times (I_{n+1}\cdots I_N).$

Optimal Ranks for TT decomposition II

Constrained optimization problem

min
$$\sum_{n} \alpha_{n} ||\mathbf{Z}_{n}||_{*}$$
 (54) s.t.
$$||\mathbf{Y} - \mathbf{X}||_{F}^{2} \leq \delta^{2}$$
 (55)

$$\mathfrak{X}_{(n)} = \mathbf{Z}_n, \quad n = 1.2, \dots$$
 (56)

Augmented Lagrangian function

$$\mathcal{L}(\boldsymbol{\mathcal{X}}, \mathbf{Z}_{1}, \dots, \mathbf{Z}_{N}) = \sum_{n=1}^{N} \alpha_{n} \|\mathbf{Z}_{n}\|_{*} + i_{D}(\boldsymbol{\mathcal{X}})$$

$$+ \frac{\lambda}{2} \left(\sum \|\boldsymbol{\mathcal{X}}_{< n} - \mathbf{Z}_{n} - \mathbf{T}_{n}\|_{F}^{2} - \|\mathbf{T}_{n}\|_{F}^{2} \cdots \right)$$
(57)

Linear Regression with Khatri-Rao structured matrix I

We consider the linear regression problem

$$\min_{\mathbf{X}} f(\mathbf{X}) = \frac{1}{2} \|\mathbf{Y} - \mathbf{\Phi} \mathbf{X}^{\mathsf{T}}\|_{2}^{2} + \frac{\mu}{2} \|\mathbf{X}\|_{F}^{2}, \quad \text{s.t. } \mathbf{X} = \mathbf{V} \odot \mathbf{U}$$
 (58)

where **Y** is a data matrix of size $K \times (IJ)$, Φ of size $K \times R$. The regressor, **X**, is in form of Khatri-Rao product of two matrices **V** of size $J \times R$ and **U** of size $I \times R$.

In order to solve the above constraint optimization, we define \mathcal{D} a set of matrices, \mathbf{X} , in form of the Khatri-Rao products, and an indicator function $i_{\mathcal{D}}(\mathbf{X})=0$ if $\mathbf{X}\in\mathcal{D}$, otherwise ∞ . Next, we introduce an additional variable, \mathbf{Z} , and interpret the problem as alternating projection

min
$$f(\mathbf{Z}) + i_D(\mathbf{X})$$
, s.t. $\mathbf{Z} = \mathbf{X}$ (59)

Linear Regression with Khatri-Rao structured matrix II

and solve it using the augmented Lagrangian method

$$\mathcal{L}(\mathbf{X}, \mathbf{Z}, \mathbf{T}) = f(\mathbf{Z}) + i_{D}(\mathbf{X}) + \frac{1}{2\gamma} \left(\|\mathbf{Z} - \mathbf{X} - \mathbf{T}\|_{F}^{2} - \|\mathbf{T}\|_{F}^{2} \right)$$

where $\gamma > 0$ and **T** is the dual variable. Updates of the primal variables, **Z**, **X**, and the dual variable, **T**, consist of the following iterations

$$\mathbf{Z}^{(k+1)} = \underset{\mathbf{Z}}{\text{arg min}} \ f(\mathbf{Z}) + \frac{1}{2\gamma} \|\mathbf{Z} - \mathbf{X}^{(k)} - \mathbf{T}^{(k)}\|_F^2, \tag{60}$$

$$\mathbf{X}^{(k+1)} = \underset{\mathbf{X}}{\operatorname{arg \, min}} \ i_D(\mathbf{X}) + \frac{1}{2\gamma} \|\mathbf{Z}^{(k+1)} - \mathbf{T}^{(k)} - \mathbf{X}\|_F^2$$
$$= \Pi_D(\mathbf{Z}^{(k+1)} - \mathbf{T}^{(k)}),$$

$$\mathbf{T}^{(k+1)} = \mathbf{T}^{(k)} + \mathbf{X}^{(k+1)} - \mathbf{Z}^{(k+1)}, \tag{62}$$

(61)

Linear Regression with Khatri-Rao structured matrix III

where k denotes the iteration index. The update for **X** in (61) becomes finding projection of $(\mathbf{Z}^{(k+1)} - \mathbf{T}^{(k)})$ onto \mathcal{D} .

Update of Z

Since the problem (60) is quadratic, **Z** is found in closed-form as

$$\mathbf{Z}^{(k+1)} = \underset{\mathbf{Z}}{\operatorname{arg \, min}} \ \frac{1}{2} \|\mathbf{Y} - \mathbf{\Phi} \mathbf{Z}^{T}\|_{F}^{2} + \frac{\mu}{2} \|\mathbf{Z}\|_{F}^{2} + \frac{1}{2\gamma} \|\mathbf{Z} - \mathbf{X}^{(k)} - \mathbf{T}^{(k)}\|_{F}^{2}$$
$$= (\mathbf{Y}^{T} \mathbf{\Phi} + \frac{1}{\gamma} (\mathbf{X}^{(k)} + \mathbf{T}^{(k)})) (\mathbf{\Phi}^{T} \mathbf{\Phi} + (\mu + \frac{1}{\gamma}) \mathbf{I})^{-1}.$$
(63)

Update of X

We next reshape columns, $\mathbf{z}_r^{(k+1)} - \mathbf{t}_r^{(k)}$, r = 1, ..., R to matrices \mathbf{H}_r , of size $I \times J$. From (61) and definition of the Khatri-Rao product, columns of the matrix $\mathbf{X}^{(k+1)}$ are best rank-1 approximation to the matrices,

 $\mathbf{H}_r \approx \mathbf{u}_r \mathbf{v}_r^T$. This approximation has unique optimal solution and can be

Linear Regression with Khatri-Rao structured matrix IV

solved in closed-form using the truncated SVD (Eckart-Young-Mirsky Theorem).

Two-Factor Update Algorithm for CPD I

CPD

min
$$\|\mathbf{y} - [\mathbf{A}_1, \mathbf{A}_2, \dots, \mathbf{A}_N]\|_F^2$$
. (64)

We next derive a new algorithm which can eliminate the redundancy and update two factor matrices at a time. Rewrite the optimization problem by unfolding the tensor along two arbitrary modes, (n < m),

min
$$\|\mathbf{Y}_{(n,m)}^T - \mathbf{\Psi}_{n,m}(\mathbf{A}_m \odot \mathbf{A}_n)^T\|_F^2$$
 (65)

where $\Psi_{n,m} = \mathbf{A}_N \odot \cdots \odot \mathbf{A}_{m+1} \odot \mathbf{A}_{m-1} \odot \cdots \odot \mathbf{A}_{n+1} \odot \mathbf{A}_{n-1} \odot \cdots \odot \mathbf{A}_1$ is Khatri-Rao product of all but two matrices \mathbf{A}_n and \mathbf{A}_m . The minimization problem in (65) is actually the regression with the regressor in the Khatri-Rao structure presented in (58).

Roadmap

- Assumptions
- Dual decomposition
- Method of Multipliers
- Alternating Direction Method of Multipliers
- Commom patterns
- Examples
- Appendices
 - Appendix 1
 - Appendix 2

Motivations of Appendix 1

The motivation of Appendix 1 is threefold:

- present the Dual Methods introduced in Chapter 1 ("Dual decomposition") in the more general setting where the dual function is not necessarily differentiable,
- discuss the assumptions to be made on function f to get interesting properties on g for the optimization schemes,
- discuss the convergence rates in more details for such schemes.

To achieve these goals, let us first introduce the notion of (convex) **conjugate** function of f (also referred to as Fenchel conjugate), denoted f^* , and let us see how to formulate the dual problem of (1) based on f^* .

Recall on conjugate functions

Given $f: \mathbb{R}^n \to \mathbb{R}$, the function

$$f^*(s) := \max_{x \in \mathbb{R}^n} (\langle s, x \rangle - f(x))$$
 (66)

is called its conjugate, $f^*(s)$ is convex even if f is not.

Conjugates appear frequently in dual programs, as:

$$-f^*(s) = \min_{x \in \mathbb{R}^n} f(x) - \langle s, x \rangle$$

• (Zhou, 2018)if f is closed (its epigraph is closed) and convex, then $f^{**} = f$. Also

$$x \in \partial f^*(s) \iff s \in \partial f(x)^{11} \iff x \in \underset{z \in \mathbb{R}^n}{\operatorname{argmin}} f(z) - \langle s, z \rangle$$
 (67)

in the case f is closed (its epigraph is closed)and strictly convex, f^* is differentiable with gradient:

$$\nabla f^*(s) := \underset{z \in \mathbb{R}^n}{\operatorname{argmin}} f(z) - \langle s, z \rangle \tag{68}$$

122/124

 $^{^{11}\}partial f(x)$ designates the subdifferential of f at x, the set of subgradients of f at x.

Roadmap

- Assumptions
- Dual decomposition
- Method of Multipliers
- Alternating Direction Method of Multipliers
- Commom patterns
- Examples
- Appendices
 - Appendix 1
 - Appendix 2

Motivations of Appendix 2

The motivation of Appendix 2 is to threefold:

- Extend our discussion about the proximal operator and introduce the proximal operator-based optimization algorithms, the so-called Proximal algorithms!
- present the so-called Proximal gradient methods and compare it
 with Projected Gradient Method. Roughly speaking, these methods
 can be seen as the generalization of the Projected Gradient Methods
 in the case the non-differentiable part of the objective is not restricted
 to the indicator of a simple convex set.
- give a brief introduction to Dual proximal gradient methods; proximal gradient methods applied to the dual.
